

GETTING PREGNANT LAPAROSCOPY

Laparoscopy is a surgical procedure that involves insertion of a narrow telescope through a small incision in the navel. This allows visualization of the abdominal and pelvic organs including the area of the uterus, fallopian tubes and ovaries. This procedure allows determining the presence of scar tissue, endometriosis, fibroid tumors or other abnormalities of the uterus, fallopian tubes and ovaries. Any of these defects may be corrected with operative laparoscopy, which involves placing instruments through ports in the scope and additional narrow ports which are usually inserted at the top of the pubic hair line in the lower abdomen. In our setting laparoscopy is performed in the operating room under general anesthesia, which makes it possible to use larger instruments for the surgical correction of the problems if necessary. Patients are generally discharged from the clinic a few hours after surgery, or the following morning.

DIAGNOSTIC PROCEDURES FOR INFERTILITY

Non-invasive:

- History and Physical Examination
- Laboratory evaluation
- Preconceptional Counseling
- Semen Analysis
- Hormonal Testing
- Transvaginal Ultrasound
- Color Doppler and 3D sonographic imaging
- Color Doppler and 3D power Doppler hysterosalpingography (sonohysterosalpingography)

Invasive:

- Hysteroscopy
- Laparoscopy
